

AutoMind Python Course

Variables & Datatypes

10 Code Writing Practice Questions

Instructions: Write clean, working Python code for each question below. Add comments where helpful, test your code, and make sure variable names are meaningful. Attempt all questions before checking solutions.

PRACTICE QUESTIONS

Q1. Declare & Print

Create two variables to store your name and age. Print them using a simple f-string sentence.

Your code:

Q2. Type Checking

Create one variable each of type int, float, and str. Use type() to print the datatype of each.

Your code:

Q3. Simple Addition

Create two integer variables a = 5 and b = 10. Print their sum.

Your code:

Q4. Type Casting

Take a variable num_str = "25" and convert it into an integer. Then print its value and its type.

Your code:

Q5. Boolean Basics

Create a boolean variable is_sunny = True. Print its value and its type.

Your code:

Q6. String Concatenation

Create two string variables `first_name = "Ada"` and `last_name = "Lovelace"`. Join them with a space to print a full name.

Your code:

Q7. Multiple Assignment

In a single line, assign the values 1, 2, and 3 to three variables `x`, `y`, `z` respectively, then print all three.

Your code:

Q8. Float Values

Create a float variable `price = 9.5`. Print its value along with its type using `type()`.

Your code:

Q9. Reassigning Variables

Create a variable `value = 10`. Print its type, then reassign `value = "ten"` and print its new type.

Your code:

Q10. Mini Challenge

Create variables for a student's name (`str`), age (`int`), and grade (`float`). Print a simple sentence using an f-string that includes all three.

Your code:
